There is a very common pattern in Ruby:

```ruby
object.method do |variable_name|
  variable_name doing something
end
```

Many times in fact the name of the object is so self explanatory that we don't care about the name of the variable of the block. It is common to see things like:

```ruby
@my_sons.each { |s| s.sell_to_someone }
```

or

```ruby
Account.all.each { |a| my_account << a.money }
```

People tend to choose `s` or `a` because we have the class or the object name just there to remind you about the context.

I would like to know if can be a good idea to have a default name for that parameter. I think it is Groovy that does something like:

```ruby
Account.all.each { my_account << it.money }
```

Where it is automagically filled and it doesn't need to be declared.

I think it is as readable or more (for newbies who don't know what is ||) and we save some typing :)
I would like the feature, but we have many things to think about.

We would not be able to make "it" a reserved keyword because that would destroy all existing RSpec code written in tens of thousands of projects.

If "it" were to be implemented as a method, how could we make it work inside of a BasicObject instance? What if a method of the same name was defined?

If "it" were to be implemented as a local variable, should its name be included in local_variables?

All things considered, I guess the variable name would have to be $-something, if any.

This is a very interesting idea but at the same time, it's difficult to keep compatibility. At least simple addition of it does not work well.

Matz.

I have one idea. We can use \it (backslash-it) or \1 instead of it. \1 means the first argument and \n refers nth argument.

\-something is not used, but \ means line continuation.

I also like the idea in principle, largely because I can relate to the idea. I encounter this every now and then when writing ruby code, in that I want a simple way to access a concept or argument.

For example, consider ruby code like this:

```ruby
object_that_responds_to_each.each { |x|
object_that_responds_to_each.each { |this_file|
```

Both variants essentially are the same here, e.g. we iterate over a collection, and we refer to the content through the name for the block parameter. In the first case, I use x as name of that variable; in the second, I use the longer this_file name.

The second variant is a bit more understandable, I think, e.g. if we iterate over the content of a directory, such as vir Dir['*'] or something like that. Then it may be easier to understand to do things such as:

```ruby
if File.file? this_file
or, if we don't know that it is a file yet, I tend to call it entry:
if File.file? entry
```

Still, this variant is shorter:

```ruby
if File.file? x
```

The first variant, aka the variant with "x", or any other single letter, including ".", is something I use A LOT, and the reason is actually because it is shorter and simpler to type for me.

There are trade-offs between readability and ease-of-use, and since I am quite a lazy person, I often use the first, shorter variant. (I do so less when there is more than
one block parameter, but sometimes I do too, such as via iterator.each [a, b, c, d ]).

Matz mentioned above that compatibility is an issue, but if we ignore this for the moment,
I really think that the proposal is a very interesting one. So I support the idea behind
the suggestion (not necessarily that particular implementation, but the idea).

As for the specific syntax change, such as in:

Account.all.each { |a| my_account << a.money }
Account.all.each { my_account << it.money }

I have no particular pro or con opinion.

I think the first old variant, the status quo, while longer, is more explicit; in the
second variant there is a bit more "magic", unless we know that "it" would refer to the
first block parameter.

I am not sure if "it" is the ideal name, but I think the idea has merits on its own,
irrespective of which name is ultimately chosen or which concept. (May have to be some
special object perhaps, that is like an array, so we could do ... it[0] it[1] too... if
we can access more than one parameter; and perhaps also support it.method_call_here,
but again, these are mostly specific details I think.)

Also I would like to mention that in the much longer case, such as this one here:

object_that_responds_to_each.each {||this_file|

I may have more variables like:

object_that_responds_to_each.each {||this_file, that_directory, that_thing|

And previously before, I also wanted a programmable way to refer to the first,
second, and third block parameter, something short like the regex $1, $2, $3.

I like the short global regex variables, such as $1 or $2, mostly because it is so
trivial to refer to them. MatchData also allows for this e. g. [0], [1] and so
forth, but I found that typing $1, $2 is so much easier.

I also wanted to have a programmatic way to access block parameters, similar to
$1, $2 - but I was unable to come up with a good syntax proposal. (All proposals
should ideally be short, because if they are long then they have a smaller net
benefit. $1 is short; [0] is a bit longer; even longer names are diminishing
some of the advantage, since we ideally need to type less, rather than more.)

So I think one big advantage of the proposal is that we could drop block parameters,
if we were to have some implicit default (and one advantage with "it", even
though the name may not be perfect, is that it is very short to type).

To the suggestion of "it", specifically - I do not like it mostly because I think \ is
not a very good character there. I disliked that in PHP for namespaces, even though
I have not really used PHP since a long time.

If the question would be between "it" and "it" then I would pick the second variant,
"it."

But I am not sure about the name "it" as such - perhaps we may have to refer to some
general new name that can refer to the internal of a block? A bit like "self" but only
specific for block variables or something like that? I can't come up with a good name
though. Perhaps it is ok to call this "it" informally for the time being, even though I
am not sure it is a great name. But whatever the name, I think it should be short. "self" is
quite short. yield_self was never that short but I think matz added an alias to
yield_self some time ago (if it is "then", which has the advantage that it is short,
even though yield_self may be more explicit. But is significantly longer.).

Anyway, apologies for the length of my comment; I think the idea is a good one. If it
can not happen before ruby 3.x, perhaps we can aim for it in a long path towards ruby
4.x (if we can have more incompatibilities along the way).

"_" is special there. it doesn't cause Syntax Error
like you can do this iterator.each {[a, _, c, _]}
but iterator.each {[a, x, c, x]} does crash

At least simple addition of it does not work well.

If we want to support implicit block arguments, in order to best keep compatibility, we would probably want to add support for new syntax, using something that is currently a syntax error. knu mentioned $-something, but I think in most cases that would not be a syntax error. One possible option is a bare @ for the implicit block argument:

Account.all.each { my_account << @.money }

This could be extended to support multiple block arguments:

{1=>2, 3=>4}.map { @1 + @2 }
# => [3, 7]

I'm not sure it's a good idea to support this, especially for multiple block arguments, because it can make code harder to understand. In a lot of cases, variable names used in blocks are helpful when reading code to understand what the code is doing. Granted, if you are using single letter variable names for block arguments, switching to this syntax for implicit arguments would not result in much loss of understanding.

Another issue with implicit block arguments would be arity:

lambda{ @ }.arity # 0 or 1?
lambda{ [@1, @2] }.arity # 0 or 2?
lambda{ @2 }.arity # 0 or 2?
s = '&2'
lambda{ eval s }.arity # ???

I still feel weird when I see @ and @1 etc. Maybe I will get used to it after a while.

I like the ampersand prefix of Elixir:

Enum.map [1, 2, 3], &(&1 + &2) # => [3, 4, 5]
Enum.reduce [1, 2, 3], &(&1 + &2) # => 6

The ampersand (&) relates more to a block in Ruby than an at-sign (@) which is associated with an instance variable context. So my preferred syntax for Ruby would be:

[1, 2, 3].map { &1 + &2 } # => [3, 4, 5]
[1, 2, 3].reduce { &1 + &2 } # => 6

But I'm not sure if this could be realized without syntax conflicts.

The problem with that is the syntax can be valid Ruby already, so it could break backwards compatibility:

```ruby
class Integer
  def to_proc
    proc{|v| self + v}
  end
end
```

Numbered parameters [Feature #4475]

#17 - 03/18/2019 11:42 AM - shevegen (Robert A. Heiler)
I think @1 @2 is ok, syntax-wise; it reminds me of $1 $2 for regex matching.

The main two advantages I see is that it is short to type; and also easy to remember.

There is only one thing that I would like to add and this came from examples I saw elsewhere; in that the suggestion seems to allow us to completely omit specifying parameters in blocks, like:

collection.each { |a, b, c| }

versus

collection.each {}

Can we use @1 @2 in both variants?

I think I may have had a slightly similar suggestion to the one listed here above 8 years ago, but my thought was that we'd still have to specify the names to the parameter (variables), so I thought we would use something like:

collection.each { |long_name_a, long_name_b, long_name_c| 
  pp @1 
  pp @3 
}

I do not mind either way, by the way - but when it comes to documentation and also examples, I think it would help to mention it up front which variant(s) people could use. The best may be to allow flexibility in both variants, e.g. to specify the name of the parameters, but to also be able to omit it, while still being able to use the positional targeting here, such as through @1 @2 and so forth. And, if this is the case, to also give an example or two in the main documentation for this functionality.

Thanks.

Would it be possible to make this more inline with other "magic" variables? Such as $1 and $2 for regex. Maybe $blockarg1 and $blockarg2?

#19 - 03/18/2019 05:12 PM - bozhidar (Bozhidar Batsov)
I also dislike the use of @ for this. It looks very weird and evokes strong references to instance variables in my mind. I'm not sure which characters exactly are an option, but I think we should avoid the use of @. Will something like %1 work? (that's what Clojure uses, which % being the same as
%1.

In general I question the need for this and its usefulness, as short names are usually useful only in short blocks with 1/2 params, otherwise the readability of the code is impacted a lot. We already have a good shorthand for blocks with one param (at least in the most common case), so it feels to me we're complicated the parser/syntax without a very strong case for doing so. Many features are useful to some extent, but we should also keep in mind that none of them come for free.

#20 - 03/18/2019 10:48 PM - gkemmey (Gray Kemmey)

Is there a reason to do this other than to save some typing? I'm not sure we've proposed any terribly real-world cases here where this made code better.

I feel like we already have some single-character patterns around blocks with one or two arguments, that aren't that onerous to type and still convey meaning. For example:

```
10.times { |i| ... } # i for index
10.times { |n| ... } # n for number
[1, 2, 3].map { |n| ... } # n for number
[1, 2, 3].map { |e| ... } # e for element
['one', 'two'].map { |s| ... } # s for string
[1, 2, 3].each_with_index { |e, i| ... } # e for element, i for index
[].each { |k, v| ... } # k for key, v for value
[[], [[]]each { |r, c| ... } # two-d arrays: r for row, c for column
File.open('') { |f| ... } # f for file
```

For anything more complex, is it bad too have to name your arguments?

In no particular order, some downsides I see:

1. It adds some cognitive load to remember the position of arguments. Like in the {}.each example -- is @1 the key or the value? It's obvious when using k and v which is which.
2. It blurs the line between instance variables.
3. I don't know that we use simple blocks like this most of the time, which means, as a newcomer, you won't see this regularly, and it'll be confusing when you do. Think about the first time you saw something like [1,2,3].reduce(&:+). Was that clear to anyone? (Though in the & case, certainly worth the complexity.)
4. It's always a little strange when things like this aren't 0-based, right?
5. Personally, find it a little jarring to iterate over an array and then use @1 to reference each element. "At one" just feels positional (like an index).

Anyway, this seems like it adds a fair amount of complexity and sacrifices a lot of readability, just to save ~2 characters. Happy to hear why I'm wrong though...

#21 - 03/22/2019 12:19 AM - HarlemSquirrel (Kevin McCormack)

As I'm reading through this I am warming up to this idea. However, I would prefer to keep @ for instance variables.

Ruby currently does not allow naming variables or methods starting with a number. Could we utilize this?

```
enumerable_object.map { |a| method(2a) + 3a * 4a }
```

The a in 1a, 2a, etc. could be thought of as an abbreviation for "argument".

I might also suggest that the sequence start with 0a since we have what feels like an "array" of parameters and array indexes begin at 0.

```
enumerable_object.map { "#{0a} comes before #{1a}" }
```

Exactly my thought: Why? what will this make better or easier?
IMHO it does exactly the opposite, it makes Ruby harder to read. By introducing @vars that are NOT instance vars. Code will be harder to read and understand (if it has an @ and starts with a number it is this, otherwise it is that). It saves some typing but short block-vars already possible now:

```ruby
each { |a| puts a }
vs.

each { puts @1 }
```

I love ruby because it allows me to write concise and readable code. Naming variables is part of this.
