This looks very interesting! Would someone be willing to translate to english? I've only got a vague idea of what is being discussed.

Hi,

I should have posted in English at first.
Thank you guys for translation.

```
                            matz.
```

Do I need to learn Ruby first to learn Rails?

Loving Ruby and want to learn it.

Thanks

#6 - 10/18/2011 02:31 PM - Anonymous

Thanks for the translation!

I've got a question about the proposal that will help me understand how it would be implemented.

Given a method:

```
def foo(name, age)
p [name, age]
end
```

And then code that calls this method:

```
arg = { :name => "Evan", :age => 32 }
foo(arg)
```

Would this print out ["Evan", 32]?

If so, this seems like a very big change that a lot of code written against 1.9 will not work with.

Also, the example code in the proposal uses a form to call foo like this:

```
foo(name: "Evan", age: 32)
```

This reuses the 1.8/1.9 behavior of the implicit hash parameter. Does this mean that the implementation creates a hash on the caller side, which is then pulled apart by the called method? If so, these seems just like my first example, and would end up breaking a lot of code.

Because 1.9 introduces the new hash syntax, which programmers have begun using with the implicit hash parameter, I don't think that the syntax can be used again for keyword arguments without introducing an incompatible change.

So, I'd like to suggest an alternative to this which uses a different (and thusly unambiguous) syntax:

```
foo(name="Evan", age=32)
```

I know that this is valid ruby code in 1.9, but it is extremely rare, much much more rare than the implicit hash parameter. Thusly it is safer and will not break 1.9 code.

This form also allows for an implementation of keyword parameters that don't require creating a Hash object, which makes the code faster and more useful.

If a truly new syntax must be introduced to be 100% backward compatible, I'd suggest:

foo(name := "Evan", age := 32)

:= is already known in computing as a bind operator, and thus it is suited well to this task.

Thank you for considering my proposal.

- Evan

#7 - 10/18/2011 02:31 PM - rkh (Konstantin Haase)

Please ask such question at the Rails mailing list, the ruby-talk mailing list, or Stack Overflow. The core list is about developing Ruby, not developing *in* Ruby.

Konstantin

#8 - 10/18/2011 02:53 PM - rkh (Konstantin Haase)

From the current patch it seems to me that this would raise an ArgumentError, as it does now. Neither name nor age are "keyword arguments". There is no way to define keyword arguments without a default.

Also, these are really named arguments in a Python sense, not keyword arguments in a Smalltalk sense.

matz (Yukihiro Matsumoto):

```
def foo(bar: 42) bar end
foo bar: nil
```

The above should return nil IMHO, since this is also what I'd expect if it would be an options hash.

Konstantin

> Ah! Ok, so keyword arguments are completely separate than normal arguments. This feature would basically be "Hash restructuring", ie letting the VM know what keys in the Hash your interested in and having it pull them out for you.

That seems quite interesting, but less useful that being to invoke a method and bind a value to a normal argument via it's name.

I just wanted to point out that MacRuby (in order to support compatibility with Obj-C which uses Smalltalk style keyword arguments) already uses the hash syntax for defining/calling methods, but the semantics are different from what is being proposed here, if I understand correctly. To summarize:

```
# Ruby 2.0 proposal:
def foo(a: 1, b: 2, c: 3)
    puts [a, b, c]
end
foo(a: 'one', b: 'two', c: 'three') #=> ["one", "two", "three"]
```

```
# Currently in MacRuby:
def foo(a: first, b: second, c: third)
    puts [first, second, third]
end
foo(a: 'one', b: 'two', c: 'three') #=> ["one", "two", "three"]
```

With the current proposal for keyword arguments, I think MacRuby would not be able to implement this feature.

I know. But I have warned MacRuby guys for years.

```
                          matz.
```

Hi,

In message "Re: [ruby-core:40209] Re: [Ruby 2.0 - Feature #5454] keyword arguments"
on Wed, 19 Oct 2011 00:31:44 +0900, Yusuke Endoh mame@tsg.ne.jp writes:

|Interesting. Matz, which do you prefer?

I prefer the former (keyword hash) way. MacRuby keyword arguments are
solely for bridging with Objective-C, so that they can translate

obj.foo(1, bar: 2)

into

[obj foo: 1 bar: 2]

in Objective-C.

```
matz.
```

Okay, I see you prefer the current proposal.

Still, I guess MacRuby will serve as a useful reference
when we discuss this proposal, especially, the corner cases.

Heh, indeed. I just spoke briefly with lrz, and he's optimistic that we can
make it work. One question I have, though, would be if you intend to allow
variables as default values or only literals. For example, should this work:

```
x = 30
def foo(a: 1, b: 2, c: x)
    puts [a, b, c]
end
foo(a: 10, b: 20) #=>  [10, 20, 30]
```

?

Though the example will not work because x is in the different
variable scope, you can write any expression as a default value,
like:

```
def foo(str: File.read("/etc/passwd"))
p str
end
foo(str: "bar") #=> "bar"
foo             #=> the contents of /etc/passwd
```

... currently it does not work correctly because of bug of my
implementation, though :-)
I'll update the patch tomorrow.

#17 - 10/23/2011 02:52 PM - mame (Yusuke Endoh)

- File keyword-argument-patch-20111023.zip added

- Assignee changed from matz (Yukihiro Matsumoto) to ko1 (Koichi Sasada)

Hello,

I've updated the patch (keyword-argument-patch-20111023.zip).
It modifies the core much.
So I'd like to commit it after koichi's review.

The rough strategy of the implementation is to interpret:

```
def foo(str: "foo", num: 424242, **h)
...
end
```

as:

```
def foo(*r)
h = r.last.respond_to?(:to_hash) ? r.last.to_hash.dup : {}
str = h.key?(:str) ? h.delete(:str) : "foo"
num = h.key?(:num) ? h.delete(:num) : 424242
...
end
```

> | - Do we need a way to receive all the keyword arguments?
> |
> | def foo(str: "foo", num: 424242, **h)
> | p h
> | end
> | foo(str: "bar", check: true) #=> { :check => true }
>
> It would be necessary for delegating arguments to another method.

Done.

```
$ ./ruby -e '
def foo(str: "foo", num: 4242, **h)
p h
end
foo(str: "bar", check: true)
```

'
{:check=>true}

| - When nil is passed explicitly, should the value be nil?
|
| def foo(str: "foo")
| p str
| end
| foo(str: nil) #=> nil ? (not implemented yet, "foo" is assigned now)

It should be nil.

Done.

```
$ ./ruby -e '
def foo(str: "foo", num: 4242)
p str
end
foo(str: nil)
'
nil
```

| - When unknown keyword is specified and there is no **rest,
| should we raise exception or warning?
|
| def foo(str: "foo", num: 424242)
| end
| foo(check: true) #=> ArgumentError?

There is a room for discussion. Currently I think it should raise an exception unless receiving with **rest, but I may change my opinion after using it in several situations in actual scripts.

Done.

```
$ ./ruby -e '
def foo(str: "foo", num: 4242)
end
foo(str: "bar", check: true)

'
-e:5:in `': unknown keyword (TypeError)
```

| - Should we accept an object behaves like Hash as keyword arguments?
| (Current implementation only checks T_HASH for speed)

Please use to_hash for now. Maybe we should define new method, something like to_kw.

Done.

```
$ ./ruby -e '
def foo(str: "foo", num: 4242)
p str
end
h = Object.new
def h.to_hash; { str: "bar" }; end
foo(h)
'
"bar"
```

| - Is order of arguments ok?
|
| def foo(
| a, b, c, # mandatory arguments
| opt = 1, # optional arguments
| *rest, # rest argument
| x, y, z, # post mandatory arguments
| k1: 1, k2:2, # keyword arguments
| **kh, # keyword rest argument
| &blk # block argument
|)

I think this order is OK.

Thanks!
